Where the funds sit

On-chain reading of the Notional addresses. September 2026.

This note continues the May 2024 court file with live chain data. Each bech32 address was converted across the other Cosmos chains, because one key is the same 20 bytes under every prefix. Where an account has signed, the chain publishes the public key. Those keys were compared. Celestia history was read from Celenium. Bank balances were read from public REST servers. Ethereum was read from a public execution node and from Blockscout. One Monero transaction was read from a public explorer. Stargaze's REST servers did not answer. Osmosis nodes that still answer no longer index the 2024 transaction history, so swaps on Osmosis after the Celestia bridge cannot be listed transfer by transfer.

1. What is still in a wallet

Asset	Where	Amount now
STARS from the January theft	Same key, migrated onto the Cosmos Hub	218,892.27 STARS
AKT from the 20 OSMO side swap	akash1y9yw…grf7up3	4.248 AKT
OSMO left on that key	osmo1y9yw…gxfqtwe	4.009 OSMO
Stablecoin and OSMO on the other side wallet	osmo1q0w3…vr85u2v	7.772664 USDC and 2.318 OSMO
Sei leftover	sei1r0ct…fz9enh7	1.94 SEI
BitCanna leftover on the original wallet	bcna1dl7w…ka2nq42	118.53 BCNA
The 9,008 TIA, plus staking rewards	celestia1hkqyu…m8zrv50	10,013.35 TIA, never spent
Liquid OSMO on the second Celestia operator	osmo1h3pnk…q20svh45	212,339.53 OSMO

The Hub token is the migrated Stargaze token. The chain describes it as native STARS moved from Stargaze to the Cosmos Hub. The pleaded amount was 218,900.198 STARS. This key holds 218,892.27. The eleven Bad Kid NFTs could not be checked, because Stargaze did not answer. The 4.248 AKT, 4.009 OSMO, 2.318 OSMO and 7.772664 USDC are the same remainders the May 2024 affidavit already recorded. The USDC figure is the IBC denom whose base is uusdc. The affidavit called that quantity USDT. The amounts match to the reported precision.

2. One public key did the January theft

The address the affidavit calls 1r0ct has signed on Celestia, on Osmosis, and on the Cosmos Hub. All three accounts publish the same secp256k1 public key:

```
A/lVF1N4+tI78PVAip+MxVnluWQNaZjtOu7X+M5omoG2
```

Celestia account sequence is 6. That matches six outgoing transfers, and every one of them is an IBC transfer to the same key on Osmosis. Nothing on Celestia was paid to a third party.

UTC time	TIA	Destination
2024-01-12 18:48	810	osmo1r0ct…, the same key
2024-01-24 03:39	7,000	same
2024-01-26 16:21	14,000	same
2024-02-08 16:19	10,000	same
2024-06-07 08:29	10,000	same
2024-06-07 08:40	30,000.524846	same

Those six transfers sum to 71,810.52 TIA. The pleaded theft was 71,810.596 TIA. The gap is fees. The last two transfers, on 7 June 2024, are the 40,000.59 TIA the affidavit still showed on Celestia in May 2024. The Celestia balance of this key is now 0.056 TIA. The Osmosis form of the key does not hold a TIA balance either. The later swaps that would show where that June bridge went are not in the Osmosis transaction index these public nodes still serve.

What can still be seen of the Ethereum end is the remainder the affidavit left at two wallets. On 5 May 2025, 0xE2240450744f67DD61289A6071c9E72411F20105 sent 20.394 ETH. On 8 May 2025, 0x758E54d88BDAb00bE93e89800D894ffdfF0c63C5 sent 127.69 ETH. Both payments went to the same new address, 0x4c5fb9046085153d89a19118123facc2ab813e31. That address forwarded the ether the same day, in round lots of 0.1, 1, 10 and 100 ETH, to one contract.

The Ethereum trail stops here

`0xd90e2f925DA726b50C4Ed8D0Fb90Ad053324F31b`

Blockscout name: TornadoRouter. Verified source file contracts/tornado-proxy/TornadoRouter.sol. Balance: 0 ETH.
A deposit into this contract does not identify the later withdrawal. That is the same kind of stop as Monero. The two 2024 wallets paid one address, and that address paid this contract.

On 7 November 2024, 0xE224 also sent 5 ETH to 0x34198730581e4f7318323cb22e1f95b9c97907c9, and that address sent about 6 ETH back to 0x758E the same day. It is empty now. It is a pass-through between the two wallets, not a resting place. 0xE224 now holds about 0.0016 ETH. 0x758E holds about 0.104 ETH. 0x4c5f holds about 0.014 ETH.

3. The 9,008 TIA is parked, and the key has never signed

celestia16dc…, the company wallet, sent 9,030 TIA to celestia1xvxx… at 14:10 UTC on 31 October 2023. At 17:49 it also sent 9,029.9 TIA to celestia1c35…. At 18:13, 9,009.971417 TIA came back from 1xvxx. At 18:28, 16dc sent 9,008 TIA to 1c35. The affidavit describes the 9,008. The chain also shows the earlier 9,029.9 from the same company wallet to the same destination. 1c35 then delegated 9,007.955555 TIA to the validator whose moniker is Notional.

The stake was later moved to Imperator.co. Unbonding was started and cancelled more than once, which is the pattern the affidavit described. On 19 January and 9 February 2024 the gas for 1c35 was paid by a different key, celestia1x6h3wvjwq8w0jgw7ej0fw4m57jflz4c5eqd5j3, through a fee grant. That granter key, on 19 January 2024, also cancelled an unbonding of exactly 9,123.406540 TIA at the same Imperator validator. That integer is the size of the 1c35 stake. The two keys were operating the same quantity of TIA at the same validator on the same afternoon. They are not the same public key.

In January 2025, 1c35 sent the position, grown by rewards, to celestia16q5zkf7p2dxg05jusdccc3tp78w2u4tsqxwk6v. On 20 July 2025 that key sent 10,013.345032 TIA onward.

10,013.35 TIA is still here. The account sequence is 0.

`celestia1hkqyuh38terdtcvf49kvcs4hv3kpyslm8zrv50`

Spendable 10,013.345039 TIA. Delegated 0. Unbonding 0. No public key is published, because this address has never signed a transaction. The only material message is the incoming transfer on 20 July 2025.

Smaller sums left 1c35 in January 2024 and were spent: about 6.1 TIA to celestia1phgph… and 16.55 TIA to celestia1jcxp4…, which forwarded it the same fortnight. Those are not the parked balance.

4. A second operator pooled about 18,059 TIA the next morning

On 1 November 2023, between 07:59 and 08:26 UTC, one new address received two transfers of about 9,030 TIA each and staked both to the Notional validator. The two source addresses already existed at Celestia genesis, which was the previous day. This is a different key from 1c35 and from 1r0ct.

UTC	TIA	From	What h3pnkam did
01 Nov 07:59	1.0	celestia1964u3kmj92ue9fkx54spagewecs2dfav8hf07g	Received
01 Nov 08:03	9,028.0	same genesis address	Received
01 Nov 08:05	9,028.955521	—	Delegated to the Notional validator
01 Nov 08:09	9,030.037498	celestia10djr026n642pt4taypx53rp597v646rvd3wakd	Received
01 Nov 08:26	9,029.987498	—	Delegated to the Notional validator
05 Dec 08:46	18,058.943019	—	Redelegated off Notional, to celestiavaloper1ryyz…

The receiving and staking key is:

`celestia1h3pnkamn8wx6sxv09ehw64efwecx2fq2kpwhet`

celestia10djr… is the same genesis address that, on 19 January 2024, sent 1.368 TIA to the fee-grant key that was paying gas for 1c35. So the wallet that supplied half of this 18,059 TIA also funded the key that operated alongside 1c35. That is a link between the two November staking operations. It is not a link to the 1r0ct public key. The three public keys are different.

On 20 August 2024 this key IBC-transferred 18,342.0954 TIA to itself on Osmosis, osmo1h3pnkamn8wx6sxv09ehw64efwecx2fq20svh45. The same afternoon it IBC-transferred 1,000 TIA and 998 TIA to two Penumbra addresses. Penumbra is a shielded chain. The public record shows the transfer in. It does not show where those 1,998 TIA went afterwards. That stop is the same kind as Monero.

Penumbra deposits, 20 August 2024. Not followable after the deposit.

1,000 TIA to

`penumbra1gc7glqcarndgcu4z4hdldag4ttv2gmm0ykdjgpj3vjxfpv5kyutmcvtxsltlc6q6vg906unh5mggg6znf5t5m6qmrlz5ftcadwkc3mnv2y7mh89qsyprx7a5yxyn6ljtqhvddx`

998 TIA to

`penumbra1xgufm8v9vhu0y7yfrar8c2g6ky76u52tf2l8sy55gem690t3ulvj22rnjndgljpmq8krqp33dhh8d2e6m9arytx64kdefymp4qwmye0lm4pu9saau7laajektrlal420ezhuf4`

The Osmosis form of the h3pnkam key does not still hold that TIA as TIA. It does hold 212,339.53 OSMO, plus a long list of other tokens. The public Osmosis nodes queried for this note return no indexed 2024 transactions for this address, so the trades that spent the bridged TIA cannot be listed here. The 212,339.53 OSMO is the large liquid balance on that key today. It is not, by itself, a proof of the exchange rate at which the TIA was sold.

5. The Binance feeders are two more keys

osmo1tp50… and osmo1kfzdt… have signed. Their public keys are not the 1r0ct key, and they are not each other. tp50's Osmosis sequence is 327. kfzdt's is 28. Both still hold balances. On Osmosis, tp50 is an active account: factory tokens, a pool share, and 0.478 OSMO of liquid OSMO among a longer list. On the Hub it holds 0.381 ATOM. On Juno it holds 33.86 JUNO. kfzdt holds 2.175 OSMO, 3.180 ATOM, and 15.388 STRD on Stride. These are the two wallets that, in the transactions a public Osmosis node still indexes for 2026, kept paying the Binance deposit address osmo129uhl… with memo 100603137. The chain does not show either key receiving the January 1r0ct transfers.

Key	Public key (base64)	Osmosis sequence
1r0ct	`A/lVF1N4+tI78PVAip+MxVnluWQNaZjtOu7X+M5omoG2`	73
tp50	`AqCHBI/X5BA8QD5L+yGHJpN741/X51aBwOAw/+UlAgIc`	327
kfzdt	`AqWUX0+ItcuhXrpxMHHAmip/0OfBzg3JFdxup9hndQB9`	28
1c35	`A1EhvQ4u/vuRAZkSmO1EZIbUuZUsp0si/RJxxnjYxOLf`	30 on Celestia
h3pnkam	`A2AcDEyCun5uIqhuEPS79phLQn1u5EP1TRuObk/XqNC7`	115 on Celestia

The Celestia deposit addresses pleaded as Binance and KuCoin, celestia1fd3… and celestia1cyl…, have sequences 25,275 and 36,109. They are exchange infrastructure. Balances on them today, about 3,886 TIA and 397 TIA, are exchange float.

6. Where a public lookup cannot continue

Stop	What is visible	What is not
Monero	The ten payout transactions are confirmed on chain. The first, abaa6e8e…72d99, is in block 3,060,649.	Outputs are encrypted. A hash does not show who received the XMR or where it sits. That needs the view key. It is not in the file.
TornadoRouter	127.69 ETH and 20.394 ETH reached 0x4c5f… in May 2025 and were forwarded the same day, in pool-sized lots, to the verified TornadoRouter contract.	A deposit does not identify the withdrawal.
Penumbra	1,000 TIA and 998 TIA left h3pnkam for two penumbra1 addresses on 20 August 2024.	Penumbra shielded spends are not visible from the IBC deposit.
Osmosis archive	Balances and 2026 indexed sends are readable. The June 2024 and August 2024 TIA arrived on known Osmosis addresses and is not still held as TIA.	The swap-by-swap history of those bridges is not on the nodes that answered.
Stargaze	The fungible STARS of the 1r0ct key is on the Hub, under the migration token.	The NFT module did not answer, so the Bad Kids are unchecked.

7. What this says about people

The chain supports several operators. It does not print a legal name on the January theft key, on the parked TIA address, or on h3pnkam.

One public key, 1r0ct, took the January assets, bridged the TIA only to itself, still holds the STARS, and the Ethereum remainder of that path was swept in May 2025 by one address into TornadoRouter. That is one operator for that path, continuous from January 2024 through the 2025 sweep.

A different set of keys handled TIA on 31 October and 1 November and staked it to the validator named Notional. 1c35 received the 9,008 from the company wallet and the coins now sit, unspent, on hkqyuh. h3pnkam pooled two genesis-address transfers of about 9,030 TIA each and staked them to that same validator within twenty minutes. The genesis address 10djr supplied h3pnkam and, two months later, funded the key that paid gas for 1c35. The affidavit says Long and Du controlled 1c35 while they were employed. The chain shows the later hops. It does not write their names on hkqyuh or on h3pnkam.

The BitCanna proceeds were cashed through Binance user 53164342, the account in the name NGÔ TAT THÀNH, which had sent a test transaction to the hostile wallet first. tp50 and kfzdt are two further keys that kept paying that account's Osmosis deposit address into 2026. They are not the 1r0ct key. The 10 TIA test is the other Binance identity, TRINH THI DINH. Nothing on chain joins that account to 53164342.

Read together, the public record is a small number of keys with different jobs: one theft key that still holds the STARS and that later used TornadoRouter, a cluster that staked to Notional's validator and parked 10,013 TIA, two feeder keys on the Binance cash-out, and a separate same-day account for the 10 TIA. Monero, TornadoRouter, and Penumbra are the three places that cluster disappears from public view.

Sources: Celenium message history for Celestia; LavenderFive and other public REST servers for bank balances and published public keys; ethereum.publicnode.com and Blockscout for Ethereum balances, transaction lists, and the verified contract name; xmrchain.net for the existence of one Monero transaction. Figures are the chain's, at the time of this read. They are not a finding that any named person holds a key.
